## **Abstract**

This paper derives the best linear unbiased prediction (BLUP) for an unbalanced panel data model. Starting with a simple error component regression model with unbalanced panel data and random effects, it generalizes the BLUP derived by Taub (1979) to unbalanced panels. Next it derives the BLUP for an unequally spaced panel data model with serial correlation of the AR(1) type in the remainder disturbances considered by Baltagi and Wu (1999). This in turn extends the BLUP for a panel data model with AR(1) type remainder disturbances derived by Baltagi and Li (1992) from the balanced to the unequally spaced panel data case. The derivations are easily implemented and reduce to tractable expressions using an extension of the Fuller and Battese (1974) transformation from the balanced to the unbalanced panel data case.

# 1 Introduction

Panel data is usually unbalanced or unequally spaced due to lack observations on households not interviewed in certain years or firms not filing their data survey forms for a particular period. Even daily stock price data has no observations when the market is closed due to holidays or weekends. The unequally spaced pattern is also useful for repeated sales of houses that are not sold each year but at irregularly spaced intervals. It is also a common problem for longitudinal surveys and household surveys in developed as well as developing countries, see examples of these in Table 1 of McKenzie (2001) as well as Table 1 of Millimet and McDonough (2017). Unbalanced panel data estimation and testing has been studied in econometrics, see Chapter 9 of Baltagi (2013a) and the references cited there. This paper focuses on forecasting with unbalanced panel data. In particular, the paper starts by extending the best linear unbiased predictor (BLUP) derived by Taub (1979) for the random effects error component model from balanced to unbalanced panel data models. Next, the BLUP for the unequally spaced panel data with serial correlation of the AR(1) type in the remainder disturbances, considered by Baltagi and Wu (1999) is derived. This extends the BLUP for the random effects model with serial correlation of the AR(1) type derived by Baltagi and Li (1992) from balanced panels to unequally spaced panels. Unbalanced panel data can be messy. This paper keeps the derivations simple and easily tractable, using the Fuller and Battese (1974) transformation extended from the balanced to the unbalanced panel data case.

## 2 The Best Linear Unbiased Predictor

Consider an unbalanced panel data regression model:

$$y_{it} = X'_{it}\beta + u_{it} \tag{1}$$

for  $i = 1, \dots, N$ ;  $t = 1 \dots, T_i$ . The  $i$  subscript denotes, say, individuals in the cross-section dimension and  $t$  denotes years in the time-series dimension. The panel data is unbalanced since there are  $N$  unique individuals and individual  $i$  is only observed over  $T_i$

time periods.<sup>1</sup> The regressor  $X_{it}$  is a  $K \times 1$  vector of the explanatory variables and  $\beta$  is a  $K \times 1$  vector of coefficients. In an earnings equation in economics, for example,  $y_{it}$  is log wage for the  $i$ th worker in the  $t$ th time period.  $X_{it}$  may contain a set of variables like age, experience, tenure, and whether the worker is male, black, etc. In most of the panel data applications, the disturbances follow a simple one-way error component model with

$$u_{it} = \mu_i + v_{it} \tag{2}$$

where  $\mu_i$  denotes the *unobservable* time-invariant individual specific effect, such as ability.  $v_{it}$  denotes the remainder disturbance that varies with individuals and time, see Baltagi (2013a). Let  $n = \sum_{i=1}^N T_i$ . In vector notation, Equations (1) and (2) can be written as

$$y = X\beta + u \tag{3}$$

and

$$u = Z_\mu \mu + v \tag{4}$$

where  $y = (y_{11}, \dots, y_{1T_1}, y_{21}, \dots, y_{2T_2}, \dots, y_{N1}, \dots, y_{NT_N})'$  is an  $n \times 1$  vector of observations stacked such that the slower index is over individuals and the faster index is over time.<sup>2</sup> Other vectors or matrices including  $X$ ,  $u$  and  $v$  are similarly defined.  $\mu = (\mu_1, \dots, \mu_N)'$  is an  $N \times 1$  vector. The selector matrix  $Z_\mu = \text{diag}[\iota_{T_i}]$  is a matrix of ones and zeros, where  $\iota_{T_i}$  is a vector of ones of dimension  $T_i$ . It is simply the matrix of individual dummies that one may include in the regression to estimate the  $\mu_i$  if they are assumed

---

<sup>1</sup>The data is assumed to be missing at random. This in turn allows the missingness of the data scheme to be ignorable in the language of Little and Rubin (2002).

<sup>2</sup>This pattern of unbalancedness does not have to be from  $1, 2, \dots, T_i$ . In fact, these  $T_i$  observations can be for any subset of the observed time series period. This pattern is used to make the derivation easy and tractable and follow similar derivations for the balanced case. A more general pattern of unbalancedness can be used. In fact, section 2 extends this to the unequally spaced panel data with serial correlation across time considered by Baltagi and Wu (1999). A two-way error component model with a general type of missing data is considered in Wansbeek and Kapteyn (1989).

to be fixed parameters. Define  $P = Z_\mu(Z'_\mu Z_\mu)^{-1}Z'_\mu$ , which is the projection matrix on  $Z_\mu$ . In this case,  $Z_\mu Z'_\mu = \text{diag}[J_{T_i}]$ , where  $J_{T_i}$  is a matrix of ones of dimension  $T_i$ . Let  $\bar{J}_{T_i} = J_{T_i}/T_i$ . Hence  $P$  reduces to  $\text{diag}[\bar{J}_{T_i}]$ , which averages the observation across time for each individual over their  $T_i$  observations. Similarly,  $Q = I_{NT} - P$  is a matrix which obtains the deviations from individual means. For example, if we regress  $y$  on the matrix of dummy variables  $Z_\mu$ , the predicted values  $Py$  have a typical element  $\bar{y}_i = \sum_{t=1}^{T_i} y_{it}/T_i$  repeated  $T_i$  times for each individual.  $Qy$  gives the residuals of this regression with typical element  $y_{it} - \bar{y}_i$ .

For the *random effects* model,  $\mu_i \sim \text{IID}(0, \sigma_\mu^2)$ ,  $v_{it} \sim \text{IID}(0, \sigma_\nu^2)$  and the  $\mu_i$  are independent of the  $v_{it}$  and  $X_{it}$  for all  $i$  and  $t$ . The variance-covariance matrix of the disturbances is given by

$$\Omega = E(uu') = \sigma_\mu^2 \text{diag}[J_{T_i}] + \sigma_\nu^2 \text{diag}[I_{T_i}] = \text{diag}[\omega_i^2 \bar{J}_{T_i} + \sigma_\nu^2 E_{T_i}] \quad (5)$$

where  $\omega_i^2 = T_i \sigma_\mu^2 + \sigma_\nu^2$ , and  $E_{T_i} = I_{T_i} - \bar{J}_{T_i}$ . Using the fact that  $\bar{J}_{T_i}$  and  $E_{T_i}$  are idempotent matrices that sum to the identity matrix  $I_{T_i}$ , it is easy to verify that

$$\Omega^{-1} = \text{diag}\left[\frac{1}{\omega_i^2} \bar{J}_{T_i} + \frac{1}{\sigma_\nu^2} E_{T_i}\right] \quad (6)$$

and

$$\Omega^{-1/2} = \text{diag}\left[\frac{1}{\omega_i} \bar{J}_{T_i} + \frac{1}{\sigma_\nu} E_{T_i}\right] \quad (7)$$

see Wansbeek and Kapteyn (1982). Now a GLS estimator can be obtained as a weighted least squares following Fuller and Battese (1974). In this case one premultiplies the regression model in Equation (3) by  $\sigma_\nu \Omega^{-1/2} = \text{diag}\left[\frac{\sigma_\nu}{\omega_i} \bar{J}_{T_i} + E_{T_i}\right] = \text{diag}[I_{T_i} - \theta_i \bar{J}_{T_i}]$  where  $\theta_i = 1 - (\sigma_\nu/\omega_i)$ . GLS becomes OLS on the resulting transformed regression of  $y^*$  on  $X^*$  with  $y^* = \sigma_\nu \Omega^{-1/2} y$  having a typical element  $y_{it}^* = y_{it} - \theta_i \bar{y}_i$ , and  $X^* = \sigma_\nu \Omega^{-1/2} X$  defined similarly.

For the  $i$ th individual, we want to predict  $S$  periods ahead. As derived by Goldberger

(1962), the best linear unbiased predictor (BLUP) of  $y_{i,T_i+S}$  for the GLS model is

$$\hat{y}_{i,T_i+S} = X'_{i,T_i+S} \hat{\beta}_{GLS} + w' \Omega^{-1} \hat{u}_{GLS}, \quad (8)$$

for  $S \geq 1$ , where  $\hat{\beta}_{GLS}$  is the GLS estimator of  $\beta$  from equation (3),  $w = E(u_{i,T+S}u)$ ,  $\Omega$  is the variance-covariance structure of the disturbances, and  $\hat{u}_{GLS} = y - X\hat{\beta}_{GLS}$ . Note that we have  $u_{i,T_i+S} = \mu_i + \nu_{i,T_i+S}$  for period  $T_i + S$  and hence  $w' = \sigma_\mu^2(0, \dots, \iota'_{T_i}, 0, \dots, 0)$ . In this case

$$w' \Omega^{-1} = \sigma_\mu^2(0, \dots, \iota'_{T_i}, 0, \dots, 0) \text{diag} \left[ \frac{1}{\omega_i^2} \bar{J}_{T_i} + \frac{1}{\sigma_\nu^2} E_{T_i} \right] = \frac{\sigma_\mu^2}{\omega_i^2} (0, \dots, \iota'_{T_i}, 0, \dots, 0) \quad (9)$$

since  $\iota'_{T_i} \bar{J}_{T_i} = \iota'_{T_i}$  and  $\iota'_{T_i} E_{T_i} = 0$ . The last term of BLUP becomes

$$w' \Omega^{-1} \hat{u}_{GLS} = \frac{T_i \sigma_\mu^2}{\omega_i^2} \bar{u}_{i.,GLS}, \quad (10)$$

where  $\bar{u}_{i.,GLS} = T_i^{-1} \sum_{t=1}^{T_i} \hat{u}_{it,GLS}$ . Therefore, the BLUP for  $y_{i,T+S}$  corrects the GLS prediction by a fraction of the mean of the GLS residuals corresponding to that  $i$ th individual over the  $T_i$  observed periods. This BLUP was derived by Taub (1979) for the balanced panel data case. Note that it is based on the true variance components. In practice, we need to estimate the variance components to get feasible GLS and a feasible BLUP. Methods for estimating the variance components for the unbalanced panel data model are described in more details in Baltagi (2013a). To account for the additional uncertainty introduced by estimating these variance components, Kackar and Harville (1984) proposed inflation factors for the predictor.

Although this derivation has albeit a restrictive form of missing observations, for example, the time series has no gaps, the results still hold for the Fuller and Battese (1974) transformation and the Goldberger (1962) BLUP derivation even with time series gaps. This is because the individual effects are independent and the idiosyncratic error terms are not correlated across time. Also, as footnote 2 states, the pattern of missing observations can be more general, all that matters is that individual  $i$  be observed for only  $T_i$  periods and these can be any subset of the observed sample period.

For a recent survey of the BLUP literature mostly for balanced panel data in econometrics, see Baltagi (2013b). The BLUP methodology in statistics has been used extensively

in biometrics, see Henderson (1975). Harville (1976) showed that BLUP is equivalent to Bayesian posterior mean predictors with a diffuse prior. Robinson (1991) has an extensive review of how BLUP can be used for example to remove noise from images and for small-area estimation. It can be also used to derive the Kalman filter. For several applications of forecasting with panel data in economics and related disciplines, see the handbook of forecasting chapter by Baltagi (2013b) and the references cited there.

In the next section, we revisit the unequally spaced panel data model with AR(1) type remainder disturbances, considered by Baltagi and Wu (1999). While the Fuller and Battese (1974) transformation for that model was derived in that paper, the Goldberger (1962) BLUP was not given. For forecasting purposes, we derive a simple to compute expression of this predictor and show that it reduces to the usual BLUP under several special cases.

### 3 Unequally Spaced Panel Data Model with AR(1) type remainder disturbances

Baltagi and Wu (1999) considered an unequally spaced panel data model with *both* random effects and serial correlation of the AR(1) type in the remainder disturbances. To be specific,  $\mu_i \sim \text{IID}(0, \sigma_\mu^2)$  and is assumed to be independent of the remainder disturbances  $v_{it}$ . In this case,  $v_{it}$  follows an AR(1) process given by

$$v_{it} = \rho v_{i,t-1} + \epsilon_{it} \tag{11}$$

for  $t = 1, \dots, T_i$ , where  $\epsilon_{it} \sim \text{IID}(0, \sigma_\epsilon^2)$  and  $|\rho| < 1$ . For the initial value, we assume  $v_{i0} \sim (0, \sigma_\epsilon^2 / (1 - \rho^2))$ . For each individual  $i$ , one observes the data at times  $t_{i,j}$  for  $j = 1, \dots, n_i$ . Furthermore, we have  $1 = t_{i,1} < \dots < t_{i,n_i} = T_i$  for  $i = 1, \dots, N$  with  $n_i > K$ . This is a general form of unbalanced panel data which encompasses the case in Section 1. For  $i = 1, \dots, N$ , we have

$$u_i = \mu_i t_{n_i} + \nu_i, \tag{12}$$

where  $u'_i = (u_{i,t_{i,1}}, \dots, u_{i,t_{i,n_i}})$ ,  $v'_i = (v_{i,t_{i,1}}, \dots, v_{i,t_{i,n_i}})$  and  $\iota_{n_i}$  is a vector of ones of dimension  $n_i$ . In vector forms, the disturbance term in Equation (12) can be written as

$$u = \text{diag}[\iota_{n_i}] \mu + \nu, \quad (13)$$

where  $u = (u_1, \dots, u_N)$ ,  $\mu = (\mu_1, \dots, \mu_N)$  and  $v' = (v'_1, \dots, v'_N)$ . The variance-covariance matrix of  $u$  is  $\Omega = E(uu') = \text{diag}[\Lambda_i]$ , where  $\Lambda_i = E(u_i u'_i) = \sigma_\mu^2 J_{n_i} + V_i$ ,  $J_{n_i}$  is a matrix of ones of dimension  $n_i$ , and  $V_i = E(v_i v'_i)$ . For any two observed periods, say  $t_{i,j}$  and  $t_{i,l}$ , the covariance term is given by  $\text{cov}(v_{i,t_{i,j}}, v_{i,t_{i,l}}) = \sigma_\epsilon^2 \rho^{|t_{i,j} - t_{i,l}|} / (1 - \rho^2)$  for  $j, l = 1, \dots, n_i$ . To remove the serial correlation in  $v_{it}$  and keep it homoskedastic, Baltagi and Wu (1999) introduced an  $n_i \times n_i$  transformation matrix  $C_i^*(\rho)$ , which is given by

$$C_i^*(\rho) = (1 - \rho^2)^{1/2} \times \begin{pmatrix} 1 & 0 & \dots & 0 & 0 \\ \frac{-\rho^{t_{i,2} - t_{i,1}}}{(1 - \rho^{2(t_{i,2} - t_{i,1})})^{1/2}} & \frac{1}{(1 - \rho^{2(t_{i,2} - t_{i,1})})^{1/2}} & \dots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & \frac{-\rho^{t_{i,n_i} - t_{i,n_i-1}}}{(1 - \rho^{2(t_{i,n_i} - t_{i,n_i-1})})^{1/2}} & \frac{1}{(1 - \rho^{2(t_{i,n_i} - t_{i,n_i-1})})^{1/2}} \end{pmatrix}. \quad (14)$$

Premultiplying Equation (12) by  $C_i^*(\rho)$ , we get the transformed error

$$u_i^* = C_i^*(\rho) u_i = \mu_i g_i + C_i^*(\rho) \nu_i, \quad (15)$$

where

$$g_i = C_i^*(\rho) \iota_{n_i} = (1 - \rho^2)^{1/2} \left( 1, \frac{1 - \rho^{t_{i,2} - t_{i,1}}}{(1 - \rho^{2(t_{i,2} - t_{i,1})})^{1/2}}, \dots, \frac{1 - \rho^{t_{i,n_i} - t_{i,n_i-1}}}{(1 - \rho^{2(t_{i,n_i} - t_{i,n_i-1})})^{1/2}} \right). \quad (16)$$

Baltagi and Wu (1999) showed that  $C_i^*(\rho) \nu_i \sim (0, \sigma_\epsilon^2 I_{n_i})$ , i.e.,  $C_i^*(\rho) V_i C_i^*(\rho)' = \sigma_\epsilon^2 I_{n_i}$ . The variance-covariance matrix for the transformed disturbance  $u^* = (u_1^*, \dots, u_N^*)$  is  $\Omega^* = \text{diag}[\Lambda_i^*]$ , where

$$\Lambda_i^* = C_i^*(\rho) \Lambda_i C_i^*(\rho)' = \sigma_\mu^2 g_i g_i' + \sigma_\epsilon^2 I_{n_i} = \omega_i^2 P_{g_i} + \sigma_\epsilon^2 Q_{g_i}, \quad (17)$$

with  $\omega_i^2 = g_i' g_i \sigma_\mu^2 + \sigma_\epsilon^2$ ,  $P_{g_i} = g_i (g_i' g_i)^{-1} g_i'$ ,  $Q_{g_i} = I_{n_i} - P_{g_i}$  and  $I_{n_i}$  is an identity matrix of dimension  $n_i$ . Using the fact that  $P_{g_i}$  and  $Q_{g_i}$  are idempotent matrices which are

orthogonal to each other, we have

$$\Lambda_i^{*-1/2} = (\omega_i^2)^{-1/2} P_{g_i} + (\sigma_\epsilon^2)^{-1/2} Q_{g_i} = (\sigma_\epsilon^2)^{-1/2} I_{n_i} - \left[ (\sigma_\epsilon^2)^{-1/2} - (\omega_i^2)^{-1/2} \right] P_{g_i}. \quad (18)$$

Hence,  $\sigma_\epsilon \Omega^{*-1/2} = \text{diag} \left[ \sigma_\epsilon \Lambda_i^{*-1/2} \right]$ , where  $\sigma_\epsilon \Lambda_i^{*-1/2} = I_{n_i} - \theta_i P_{g_i}$  and  $\theta_i = 1 - \sigma_\epsilon / \omega_i$ . Premultiplying  $y^* = \text{diag} [C_i^*(\rho)] y$  by  $\sigma_\epsilon \Omega^{*-1/2}$ , one gets  $y^{**} = \sigma_\epsilon \Omega^{*-1/2} y^*$ . The elements of  $y^{**}$  are given by

$$y_{i,t_i,j}^{**} = y_{i,t_i,j}^* - \theta_i g_{i,j} \frac{\sum_{s=1}^{n_i} g_{i,s} y_{i,t_i,s}^*}{\sum_{s=1}^{n_i} g_{i,s}^2}. \quad (19)$$

Baltagi and Wu (1999) proposed estimating  $\sigma_\mu^2$  and  $\sigma_\epsilon^2$  by

$$\hat{\sigma}_\mu^2 = \frac{u^{*\prime} \text{diag} [P_{g_i}] u^* - N \hat{\sigma}_\epsilon^2}{\sum_{i=1}^N g_i' g_i} \quad \text{and} \quad \hat{\sigma}_\epsilon^2 = \frac{u^{*\prime} \text{diag} [Q_{g_i}] u^*}{\sum_{i=1}^N (n_i - 1)}. \quad (20)$$

Since the true disturbances  $u^*$  are unknown, we use  $\tilde{u}_{OLS}^*$  instead, which are the OLS residuals from the (\*) transformed equation. In order to make the (\*) transformation operational, we need an estimate of  $\rho$ . Let  $\tilde{v}$  be the within residuals from  $y$  on  $X$ . Inserting zeros between  $\tilde{v}_{i,t_i,j}$  and  $\tilde{v}_{i,t_i,j+1}$  if the data between these two periods are not available, one gets a new  $T \times 1$  residual  $e_i$ . An estimate of  $\rho$  can be obtained as

$$\hat{\rho} = \frac{\frac{1}{m} \sum_{i=1}^N \sum_{t=2}^T e_{it} e_{i,t-1}}{\frac{1}{n} \sum_{i=1}^N \sum_{t=1}^T e_{it}^2}, \quad (21)$$

where  $m = \sum_{i=1}^N m_i$ ,  $m_i$  is the number of observed consecutive pairs for each individual  $i$  and  $n = \sum_{i=1}^N n_i$ .

**Theorem 1** *Assume that (i)  $\epsilon_{it} \sim iid(0, \sigma^2)$ ; (ii)  $\frac{1}{N} \sum_{i=1}^N v_{i0}^2 = O(1)$ ; (iii)  $\frac{1}{N} \sum_{i=1}^N \mu_i^2 = O(1)$ ; (iv)  $\frac{N}{m} \rightarrow 0$ . We have  $\hat{\rho} - \rho = o_p(1)$ .*

The proof is given in the Appendix. Assumptions (i), (ii) and (iii) were used in Hahn and Kuersteiner (2002). Assumption (iv)  $\frac{N}{m} \rightarrow 0$  is equivalent to  $\frac{m}{N} = \frac{1}{N} \sum_{i=1}^N m_i \rightarrow \infty$ . The consistency of  $\hat{\rho}$  requires the average number of observed consecutive pairs to be large. For balanced panel data, this condition reduces to  $T \rightarrow \infty$ . Using this estimator

of  $\rho$ , one gets a feasible GLS estimator of  $\beta$ . Detailed steps can be found in Baltagi and Wu (1999).<sup>3</sup>

Now, we return to prediction. Using the fact that the disturbances are independent across different individuals, we have  $w' = E(u_{i,T+S}u_i') = (0, \dots, E(u_{i,T+S}u_i'), 0, \dots, 0)$ , which is a vector of zeros except for the  $i$ th position. Therefore,

$$w'\Omega^{-1} = (0, \dots, E(u_{i,T+S}u_i'), 0, \dots, 0) \text{diag}[\Lambda_i^{-1}] = (0, \dots, E(u_{i,T+S}u_i') \Lambda_i^{-1}, 0, \dots, 0) \quad (22)$$

and

$$w'\Omega^{-1}\hat{u}_{GLS} = (0, \dots, E(u_{i,T+S}u_i') \Lambda_i^{-1}, 0, \dots, 0) \begin{pmatrix} \hat{u}_1 \\ \hat{u}_2 \\ \vdots \\ \hat{u}_N \end{pmatrix} = E(u_{i,T+S}u_i') \Lambda_i^{-1} \hat{u}_i, \quad (23)$$

where  $u_i' = (u_{i,t_{i,1}}, \dots, u_{i,t_{i,n_i}})$  and  $\hat{u}_i$  denote the GLS residuals. Since  $u_{i,T+S} = \mu_i + \nu_{i,T+S}$ , we can decompose equation (23) into two terms:

$$E(u_{i,T+S}u_i') \Lambda_i^{-1} \hat{u}_i = E(\mu_i u_i') \Lambda_i^{-1} \hat{u}_i + E(\nu_{i,T+S}u_i') \Lambda_i^{-1} \hat{u}_i. \quad (24)$$

Since  $\Lambda_i^* = C_i^*(\rho) \Lambda_i C_i^*(\rho)'$ , we have

$$\Lambda_i^{-1} = C_i^*(\rho)' \Lambda_i^{*-1} C_i^*(\rho) = C_i^*(\rho)' (\omega_i^{-2} P_{g_i} + \sigma_\epsilon^{-2} Q_{g_i}) C_i^*(\rho) \quad (25)$$

using Equation (18). Since  $\mu_i$  and  $\nu_i$  are independent of each other, we have  $E(\mu_i u_i') = E(\mu_i \mu_i' l_{n_i}') = \sigma_\mu^2 l_{n_i}'$ . The first term in equation (24) can be rewritten as:

$$\begin{aligned} & E(\mu_i u_i') \Lambda_i^{-1} \hat{u}_i \\ &= \sigma_\mu^2 l_{n_i}' C_i^*(\rho)' (\omega_i^{-2} P_{g_i} + \sigma_\epsilon^{-2} Q_{g_i}) C_i^*(\rho) \hat{u}_i \\ &= \frac{\sigma_\mu^2}{\omega_i^2} g_i' \hat{u}_i^*, \end{aligned} \quad (26)$$

---

<sup>3</sup>It is important to note that this is easily programmable. In fact, the Baltagi and Wu (1999) feasible GLS procedure has been implemented in Stata using `xtregar`, so it is easy to derive the BLUP from these results.

where  $C_i^*(\rho) \hat{u}_i = \hat{u}_i^*$ , using the fact  $C_i^*(\rho) \iota_{n_i} = g_i$ ,  $g_i' P_{g_i} = g_i'$  and  $g_i' Q_{g_i} = 0$ . By continuous substitution, we have

$$v_{i,T_i+S} = \rho^S v_{i,T_i} + \rho^{S-1} \epsilon_{i,T_i+1} + \cdots + \epsilon_{i,T_i+S}$$

and

$$E(v_{i,T_i+S} u_i') = E(v_{i,T_i+S} v_i') = E[(\rho^S v_{i,T_i} + \rho^{S-1} \epsilon_{i,T_i+1} + \cdots + \epsilon_{i,T_i+S}) v_i'] = \rho^S E(v_{i,T_i} v_i')$$

since  $E[\epsilon_{i,T_i+1} v_i'] = \cdots = E[\epsilon_{i,T_i+S} v_i'] = 0$ . Because  $E(v_{i,T_i} v_i')$  is the last column of the covariance matrix  $E(v_i v_i') = V_i$ , we have

$$E(v_{i,T_i+S} v_i') = \rho^S (0, \dots, 0, 1) V_i.$$

Also,  $\Lambda_i^{-1}$  in Equation (25) reduces to

$$\begin{aligned} \Lambda_i^{-1} &= C_i^*(\rho)' (\omega_i^{-2} P_{g_i} + \sigma_\epsilon^{-2} Q_{g_i}) C_i^*(\rho) \\ &= C_i^*(\rho)' [\sigma_\epsilon^{-2} I_{n_i} - (\sigma_\epsilon^{-2} - \omega_i^{-2}) P_{g_i}] C_i^*(\rho) \\ &= C_i^*(\rho)' \left[ \sigma_\epsilon^{-2} I_{n_i} - \left( \frac{g_i' g_i \sigma_\mu^2}{\sigma_\epsilon^2 \omega_i^2} \right) g_i (g_i' g_i)^{-1} g_i' \right] C_i^*(\rho) \\ &= \sigma_\epsilon^{-2} C_i^*(\rho)' C_i^*(\rho) \left[ I_{n_i} - \frac{\sigma_\mu^2}{\omega_i^2} \iota_{n_i} g_i' C_i^*(\rho) \right] \end{aligned}$$

using the fact that  $Q_{g_i} = I_{n_i} - P_{g_i}$ ,  $\omega_i^2 = g_i' g_i \sigma_\mu^2 + \sigma_\epsilon^2$  and  $g_i = C_i^*(\rho) \iota_{n_i}$ . The second term in equation (24) becomes:

$$\begin{aligned} &E(v_{i,T_i+S} u_i') \Lambda_i^{-1} \hat{u}_i \\ &= \rho^S (0, \dots, 0, 1) V_i \sigma_\epsilon^{-2} C_i^*(\rho)' C_i^*(\rho) \left[ I_{n_i} - \frac{\sigma_\mu^2}{\omega_i^2} \iota_{n_i} g_i' C_i^*(\rho) \right] \hat{u}_i \\ &= \rho^S (0, \dots, 0, 1) \left( \hat{u}_i - \frac{\sigma_\mu^2}{\omega_i^2} \iota_{n_i} g_i' \hat{u}_i^* \right) \\ &= \rho^S \hat{u}_{i,T_i} - \frac{\rho^S \sigma_\mu^2}{\omega_i^2} g_i' \hat{u}_i^* \end{aligned} \tag{27}$$

using the fact that  $\sigma_\epsilon^{-2} V_i = [C_i^*(\rho)' C_i^*(\rho)]^{-1}$  since  $C_i^*(\rho) V_i C_i^*(\rho)' = \sigma_\epsilon^2 I_{n_i}$ . Combining

equations (26) and (27), one gets

$$\begin{aligned}
& w'\Omega^{-1}\hat{u}_{GLS} \\
&= \rho^S \hat{u}_{i,T_i} + \frac{(1-\rho^S)\sigma_\mu^2}{\omega_i^2} g_i' \hat{u}_i^* \\
&= \rho^S \hat{u}_{i,T_i} + \frac{(1-\rho^S)(1-\rho^2)^{1/2}\sigma_\mu^2}{\omega_i^2} \left[ \hat{u}_{i,t_{i,1}}^* + \sum_{j=2}^{n_i} \frac{1-\rho^{t_{i,j}-t_{i,j-1}}}{(1-\rho^{2(t_{i,j}-t_{i,j-1})})^{1/2}} \hat{u}_{i,t_{i,j}}^* \right]. \quad (28)
\end{aligned}$$

Special case 1: *No missing observations*. This is the balanced panel data model with AR(1) remainder disturbance terms considered by Baltagi and Li (1992). In this case, we have  $t_{i,j} - t_{i,j-1} = 1$ ,  $T_i = n_i = T$ ,

$$g_i = (1-\rho^2)^{1/2} \left( 1, \frac{1-\rho}{(1-\rho^2)^{1/2}}, \dots, \frac{1-\rho}{(1-\rho^2)^{1/2}} \right) = (1-\rho) \iota_T^\alpha,$$

where  $\iota_T^\alpha = (\alpha, 1, \dots, 1)$  with  $\alpha = \sqrt{(1+\rho)/(1-\rho)}$ .

$$g_i' g_i = (1-\rho)^2 d^2,$$

and  $d^2 = \alpha^2 + T - 1$ . Hence  $\omega_i^2 = \sigma_\alpha^2$ , where  $\sigma_\alpha^2 = (1-\rho)^2 d^2 \sigma_\mu^2 + \sigma_\epsilon^2$ .

$$\frac{1-\rho^{t_{i,j}-t_{i,j-1}}}{(1-\rho^{2(t_{i,j}-t_{i,j-1})})^{1/2}} = \frac{1-\rho}{(1-\rho^2)^{1/2}},$$

$\hat{u}_i^* = C \hat{u}_i$ , where  $C$  is the  $T \times T$  Prais-Winsten (PW) transformation matrix

$$C = \begin{bmatrix} (1-\rho^2)^{1/2} & 0 & 0 & \cdots & 0 & 0 \\ -\rho & 1 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 & 0 \\ 0 & 0 & 0 & \cdots & -\rho & 1 \end{bmatrix}.$$

Therefore, Equation (28) reduces to

$$w'\Omega^{-1}\hat{u}_{GLS} = \rho^S \hat{u}_{i,T} + \frac{(1-\rho)(1-\rho^S)\sigma_\mu^2}{\sigma_\alpha^2} (\alpha \hat{u}_{i1}^* + \sum_{t=2}^T \hat{u}_{it}^*).$$

This is Goldberger's BLUP *extra term* derived by Baltagi and Li (1992). So, the unbalanced panel Goldberger's BLUP correction term reduces to its balanced panel counterpart in the case of AR(1) remainder disturbance terms.

Special case 2: *No random effects.* This reduces to a panel data model without individual effects, but with AR(1) remainder disturbances. In this case  $\sigma_\mu^2 = 0$ , and equation (28) reduces to

$$w'\Omega^{-1}\hat{u}_{GLS} = \rho^S \hat{u}_{i,T_i}. \quad (29)$$

This is Goldberger's BLUP *extra term* for the unbalanced panel data model with AR(1) remainder disturbances but no random individual effects. Goldberger (1962) actually considered a simple time series regression (not a panel) with AR(1) remainder disturbances.

Special case 3: *No serial correlation.* This is the unbalanced random effects model without serial correlation in Section 1. In this case  $\rho = 0$ ,  $g_i = \iota_{n_i}$ ,  $g_i'g_i = n_i$ ,  $\omega_i^2 = n_i\sigma_\mu^2 + \sigma_\epsilon^2$  and  $\hat{u}_{it}^* = \hat{u}_{it}$ . Equation (28) in this case reduces to

$$w'\Omega^{-1}\hat{u}_{GLS} = \frac{\sigma_\mu^2}{\omega_i^2} \sum_{j=1}^{n_i} \hat{u}_{i,t_i,j} = \frac{n_i\sigma_\mu^2}{\omega_i^2} \bar{\hat{u}}_{i.,GLS}, \quad (30)$$

where  $\bar{\hat{u}}_{i.,GLS} = n_i^{-1} \sum_{j=1}^{n_i} \hat{u}_{i,t_i,j}$ . This is Goldberger's BLUP *extra term* for the unequally spaced panel data model with no serial correlation. This encompasses the case derived in Section 1 with  $n_i = T_i$ ,  $\omega_i^2 = T_i\sigma_\mu^2 + \sigma_\epsilon^2$  and the extra BLUP Goldberger (1962) term reduces to the one given in Equation (10).

## 4 Monte Carlo Simulation

To study the finite sample performance of the proposed estimator of  $\rho$  as well as the performance of the corresponding predictors, we perform Monte Carlo experiments in this section. Following Baltagi, Chang and Li (1992) but with random effects, we generate the following panel model

$$y_{it} = 1 + x_{it} + \mu_i + v_{it}, \quad (31)$$

for  $i = 1, \dots, N$ ;  $t = 1 \dots, T + 1$ , where  $x_{it} = 0.1t + 0.5x_{i,t-1} + w_{it}$ .  $w_{it}$  follows a uniform distribution  $[-0.5, 0.5]$  and  $x_{i0} = 5 + 10w_{i0}$ . The individual specific effects are generated as  $\mu_i \stackrel{iid}{\sim} N(0, 10)$  and the remainder error follows an AR(1) process  $v_{it} = \rho v_{i,t-1} + \epsilon_{it}$ , where  $\epsilon_{it} \stackrel{iid}{\sim} N(0, 1)$  and  $\rho$  takes the values  $\{0, 0.3, 0.6, 0.9\}$ . As pointed out by Baltagi

et al. (1992), one can translate this starting date into an “effective” initial variance assumption regardless of when the AR(1) process started. More specifically, to check the impact the of the initial condition, we let  $v_{i0} \stackrel{iid}{\sim} N(0, \tau / (1 - \rho^2))$  where  $\tau$  varies over the set  $\{0.2, 1, 5\}$ . We generate the estimation sample such that the average time period observed is  $\bar{T} = \frac{1}{N} \sum_{i=1}^N T_i = 5, 10, 20$  or  $40$ . As shown in Table 1, we consider four different unbalanced panel data designs that are similar to those in Bruno (2005). In each design, the Ahrens and Pincus (1981) index  $\omega$ , which measures the extent of unbalancedness, is set to be 0.36 or 0.96.<sup>4</sup> In all experiments, the number of individuals is always  $N = 50$ . We perform 1,000 replications for each experiment.

Table 2 reports the bias, interquantile range (IQR), and root mean squared error (RMSE) of the estimator of  $\rho$ . Following Kelejian and Prucha (1999), *bias* is calculated as the difference between the median and the true parameter value; *IQR* is the difference between the 0.75 and 0.25 quantiles; and  $RMSE = [bias^2 + (IQR/1.35)^2]^{1/2}$ . These measures are always assured to exist, see Kelejian and Prucha (1999) for details. As shown in Table 2, when  $\bar{T}$  is small,  $\hat{\rho}$  has negative bias. However, the bias shrinks as  $\bar{T}$  increases. When  $\rho > 0$ , the bias, IQR and RMSE all decrease when  $\tau$  increases.

Tables 3-5 report the prediction performance of the following estimators: the pooled ordinary least squares (OLS), panel fixed-effects (FE) and random effects (RE) estimators that ignore autocorrelations in the error terms, and the fixed-effects and random effects estimators with AR(1) term, which are denoted as FEAR and REAR respectively. To summarize the accuracy of the forecasts, following Baltagi and Liu (2013a), we report the sampling *mean square error (MSE)*, the *mean absolute error (MAE)* and the *mean absolute percentage error (MAPE)*, which are computed as

$$MSE = \frac{1}{NR} \sum_{r=1}^R \sum_{i=1}^N d_{i,T_i+S_i}^2, \quad (32)$$

---

<sup>4</sup>See also Baltagi and Chang (1995) for more discussion on incomplete panels and this Ahrens and Pincus measure. Note that  $\omega = N / (\bar{T} \sum_{i=1}^N T_i^{-1})$ , with  $0 < \omega \leq 1$ . When the panel data is balanced  $\omega = 1$ . When the panel data is unbalanced  $\omega$  takes on smaller values.

$$MAE = \frac{1}{NR} \sum_{r=1}^R \sum_{i=1}^N |d_{i,T_i+S_i}| \quad (33)$$

and

$$MAPE = \frac{100}{NR} \sum_{r=1}^R \sum_{i=1}^N \left| \frac{d_{i,T_i+S_i}}{y_{i,T_i+S_i}} \right|, \quad (34)$$

where  $d_{i,T_i+S_i} = \hat{y}_{i,T_i+S_i} - y_{i,T_i+S_i}$ ,  $R = 1,000$  replications and we forecast the last year available for individual  $i$ .<sup>5</sup> As shown in Tables 3-5, REAR usually has the smallest MSE and MAE when  $\rho > 0$ . However, FEAR sometimes has a smaller MAPE than REAR even though the true DGP is created to be a random effect model with an AR(1) error term.

## 5 Application

In this section we illustrate the BLUP forecasts using an extract from the National Longitudinal Study data set employed by Drukker (2003). This is an unbalanced panel data over the years 1968-1988 with gaps. The data is used to illustrate the `xtreg` command in Stata and includes observations on wages for 4711 young working women who were 14–26 years of age in 1968, some with only one observation. We regressed the logarithm of wage (`lnwage`) on the woman’s age and its square (`age`, `age2`), total working experience (`exp`), tenure at current position and its square (`tenure`, `tenure2`), current grade completed (`grade`), a dummy variable for not living in a standard metropolitan statistical area (`nsmsa`), a dummy variable for living in the south (`south`) and a dummy variable for black (`black`).<sup>6</sup> we estimate the model by using the pooled OLS, FE, RE,

---

<sup>5</sup>It is worth pointing out that forecasting is not always one period ahead, as it varies by individual depending on the missing observations. In fact, the last available year for a particular individual could sometimes be several years ahead due to irregular gaps of missing data between years. This is why we gave the expression for the BLUP forecast for  $S_i$  periods ahead for individual  $i$ .

<sup>6</sup>Drukker (2003) uses this data to estimate an earnings equation to illustrate a test for serial correlation proposed by Wooldridge (2002). Experience squared was not significant and was dropped from the regression. Zero serial correlation of the first order was rejected.

FEAR and REAR respectively. In order to compute the forecasts, we focus on women who had records for at least three years. For each estimator, we compute the forecast of the logarithm of wage for the last available year for that individual. This year is not used in the estimation but is used in the computation of the three forecast performance measures. To summarize the accuracy of the forecasts, we report MSE, MAE and MAPE, which are defined in Equation (32)-(34) with  $R = 1$ . As shown in Table 6, the random effects model with an AR(1) term has the smallest MSE or MAE. While, the fixed-effects model with an AR(1) term has the smallest MAPE. This is consistent with the findings in the simulation results. For time series data sets, Diebold and Mariano (1995) derived a test to compare prediction accuracy. Recently, Timmermann and Zhu (2019) extend the Diebold and Mariano (1995) test to panel data to compare the significance of pairwise forecasts averaged over all cross-sectional units. The results of this panel data test of equal predictive accuracy is reported in Table 7. Overall, the random effects model with an AR(1) term predicts significantly better than all other models.

## 6 Conclusion

This paper derives the BLUP for the unbalanced panel data model and the unequally spaced panel data model with AR(1) remainder disturbances and illustrates these with an earnings equation using the NLS young women data over the period 1968-1988 employed by Drukker (2003) using Stata. These results can be extended to the unbalanced panel data model with AR( $p$ ) remainder disturbances, see Baltagi and Liu (2013a) for the corresponding balanced panel data case. Also, the unbalanced panel data model with MA( $q$ ) remainder disturbances, see Baltagi and Liu (2013b) for the corresponding balanced panel data case. Another extension is for the autoregressive moving average ARMA( $p, q$ ) remainder disturbances, see Galbraith and Zinde-Walsh (1995) for the balanced panel data case.

# Data Availability Statement

The data used in the paper are available on the Stata web site for all Stata users.

MAE	0.3328	0.2688	0.2674	0.2623	0.2609
MAPE	41.1100	31.0870	32.3895	30.6727	32.2694

Note: The sample is an unbalanced panel data of 3640 women over the years 1968-1988 with gaps. We compute the forecasts of logarithm wage for the last available year. In-sample model coefficient estimates are based on 22887 observations from all previous years. For the in-sample, the average available years  $\bar{T} = 6.288$  and the Ahrens and Pincus index  $\omega = 0.724$ . On average, we are forecasting  $\bar{S} = 2.131$  years ahead. MSE, MAE and MAPE are out-of-sample forecast comparison for the last available year.  $\sigma_\mu$  and  $\sigma_v$  are the standard deviations of the individual effects and remainder disturbances, respectively.  $\rho$  is the autocorrelation parameter of the remainder disturbances. LBI is the locally best invariant test statistic in Baltagi and Wu (1999). F-statistics and p-value are for the panel serial correlation test in Wooldridge (2002). Standard errors in parentheses.

Table 7: Panel Data Test Results of Equal Predictive Accuracy using the National Longitudinal Study

	OLS	FE	RE	FEAR	REAR
OLS					
FE	-10.9947				
RE	-14.4038	-3.8038			
FEAR	-11.8924	-11.6062	-0.6650		
REAR	-16.2446	-6.9276	-10.5975	-3.5953	

Note: The test statistic asymptotically follows a standard normal distribution. A negative entry means the row estimator is better than the column.

# Appendix

## Proof of Theorem 1

**Proof.** Denote  $T(1)$  as the set of observations when both  $t_{i,j}$  and  $t_{i,j-1}$  are observed.

Equation (21) could be rewritten as

$$\hat{\rho} = \frac{\frac{1}{m} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \hat{\nu}_{i,t_{i,j}} \hat{\nu}_{i,t_{i,j-1}}}{\frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \hat{\nu}_{i,t_{i,j}}^2}.$$

where

$$\hat{\nu}_{i,t_{i,j}} = \tilde{y}_{i,t_{i,j}} - \hat{\beta}_{FE} \tilde{x}_{i,t_{i,j}} = \tilde{v}_{i,t_{i,j}} - \left( \hat{\beta}_{FE} - \beta \right) \tilde{x}_{i,t_{i,j}},$$

with  $\tilde{y}_{i,t_{i,j}} = y_{i,t_{i,j}} - \bar{y}_i$  and  $\bar{y}_i = n_i^{-1} \sum_{j=1}^{n_i} y_{i,t_{i,j}}$ . Other terms such as  $\tilde{x}_{i,t_{i,j}}$ ,  $\bar{x}_i$ ,  $\tilde{v}_{i,t_{i,j}}$  and  $\bar{v}_i$  are similarly defined. Hence,

$$\begin{aligned} \hat{\rho} - \rho &= \frac{\frac{1}{m} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \hat{\nu}_{i,t_{i,j}} \hat{\nu}_{i,t_{i,j-1}}}{\frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \hat{\nu}_{i,t_{i,j}}^2} - \rho \\ &= \frac{\frac{1}{m} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \left( \hat{\nu}_{i,t_{i,j}} - \rho \hat{\nu}_{i,t_{i,j-1}} \right) \hat{\nu}_{i,t_{i,j-1}}}{\frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \hat{\nu}_{i,t_{i,j}}^2} \\ &\quad + \rho \left( \frac{\frac{1}{m} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \hat{\nu}_{i,t_{i,j-1}}^2 - \frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \hat{\nu}_{i,t_{i,j}}^2}{\frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \hat{\nu}_{i,t_{i,j}}^2} \right), \end{aligned}$$

First of all, we have

$$\begin{aligned} \frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \hat{\nu}_{i,t_{i,j}}^2 &= \frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \left[ \tilde{v}_{i,t_{i,j}} - \left( \hat{\beta}_{FE} - \beta \right) \tilde{x}_{i,t_{i,j}} \right]^2 \\ &= \frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \tilde{v}_{i,t_{i,j}}^2 + \frac{1}{n} \left[ \sqrt{n} \left( \hat{\beta}_{FE} - \beta \right) \right]^2 \frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \tilde{x}_{i,t_{i,j}}^2 \\ &\quad - \frac{2}{n} \left[ \sqrt{n} \left( \hat{\beta}_{FE} - \beta \right) \right] \frac{1}{\sqrt{n}} \sum_{i=1}^N \sum_{j=1}^{n_i} \tilde{v}_{i,t_{i,j}} \tilde{x}_{i,t_{i,j}} \end{aligned}$$

Following Lemma 7 in Hahn and Kuersteiner (2002), we can show  $\frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \tilde{v}_{i,t_{i,j}}^2 = \frac{\sigma_\epsilon^2}{(1-\rho)^2} + o_p(1)$ . Similarly, we can show that  $\frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \tilde{x}_{i,t_{i,j}}^2 = O_p(1)$ ,  $\frac{1}{\sqrt{n}} \sum_{i=1}^N \sum_{j=1}^{n_i} \tilde{v}_{i,t_{i,j}} \tilde{x}_{i,t_{i,j}} = O_p(1)$  and  $\sqrt{n} \left( \hat{\beta}_{FE} - \beta \right) = O_p(1)$  under the assumptions stated in the Theorem. Hence

$$\frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \hat{\nu}_{i,t_{i,j}}^2 = \frac{\sigma_\epsilon^2}{(1-\rho)^2} + O_p\left(\frac{1}{n}\right).$$

Similarly, we can show that

$$\frac{1}{m} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \hat{\nu}_{i,t_{i,j-1}}^2 = \frac{\sigma_\epsilon^2}{(1-\rho)^2} + O_p\left(\frac{1}{m}\right).$$

so that

$$\frac{1}{m} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \hat{\nu}_{i,t_{i,j-1}}^2 - \frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \hat{\nu}_{i,t_{i,j}}^2 = O_p\left(\frac{1}{m}\right) - O_p\left(\frac{1}{n}\right) = O_p\left(\frac{1}{m}\right).$$

Also, we have

$$\begin{aligned} & \hat{\nu}_{i,t_{i,j}} - \rho \hat{\nu}_{i,t_{i,j-1}} \\ &= \left[ \tilde{\nu}_{i,t_{i,j}} - \left( \hat{\beta}_{FE} - \beta \right) \tilde{x}_{i,t_{i,j}} \right] - \rho \left[ \tilde{\nu}_{i,t_{i,j-1}} - \left( \hat{\beta}_{FE} - \beta \right) \tilde{x}_{i,t_{i,j-1}} \right] \\ &= \left( \tilde{\nu}_{i,t_{i,j}} - \rho \tilde{\nu}_{i,t_{i,j-1}} \right) - \left( \hat{\beta}_{FE} - \beta \right) \left( \tilde{x}_{i,t_{i,j}} - \rho \tilde{x}_{i,t_{i,j-1}} \right) \\ &= \tilde{\epsilon}_{i,t_{i,j}} - \left( \hat{\beta}_{FE} - \beta \right) \left( \tilde{x}_{i,t_{i,j}} - \rho \tilde{x}_{i,t_{i,j-1}} \right), \end{aligned}$$

where  $\tilde{\epsilon}_{i,t_{i,j}} = \epsilon_{i,t_{i,j}} - \bar{\epsilon}_i$  with  $\bar{\epsilon}_i = n_i^{-1} \sum_{j=1}^{n_i} \epsilon_{i,t_{i,j}}$ . Hence

$$\begin{aligned} & \frac{1}{m} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \left( \hat{\nu}_{i,t_{i,j}} - \rho \hat{\nu}_{i,t_{i,j-1}} \right) \hat{\nu}_{i,t_{i,j-1}} \\ &= \frac{1}{m} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \left[ \tilde{\epsilon}_{i,t_{i,j}} - \left( \hat{\beta}_{FE} - \beta \right) \left( \tilde{x}_{i,t_{i,j}} - \rho \tilde{x}_{i,t_{i,j-1}} \right) \right] \left[ \tilde{\nu}_{i,t_{i,j-1}} - \left( \hat{\beta}_{FE} - \beta \right) \tilde{x}_{i,t_{i,j-1}} \right] \\ &= \frac{N}{m} \left[ \frac{1}{N} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \tilde{\epsilon}_{i,t_{i,j}} \tilde{\nu}_{i,t_{i,j-1}} \right] \\ & \quad - \frac{1}{\sqrt{nm}} \left[ \sqrt{n} \left( \hat{\beta}_{FE} - \beta \right) \right] \left[ \frac{1}{\sqrt{m}} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \tilde{\nu}_{i,t_{i,j-1}} \left( \tilde{x}_{i,t_{i,j}} - \rho \tilde{x}_{i,t_{i,j-1}} \right) \right] \\ & \quad - \frac{1}{\sqrt{nm}} \left[ \sqrt{n} \left( \hat{\beta}_{FE} - \beta \right) \right] \left[ \frac{1}{\sqrt{m}} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \tilde{\epsilon}_{i,t_{i,j}} \tilde{x}_{i,t_{i,j-1}} \right] \\ & \quad + \frac{1}{n} \left[ \sqrt{n} \left( \hat{\beta}_{FE} - \beta \right) \right]^2 \left[ \frac{1}{m} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \left( \tilde{x}_{i,t_{i,j}} - \rho \tilde{x}_{i,t_{i,j-1}} \right) \tilde{x}_{i,t_{i,j-1}} \right] \end{aligned}$$

Following Lemma 6 in Hahn and Kuersteiner (2002), we can show  $\frac{1}{N} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \tilde{\epsilon}_{i,t_{i,j}} \tilde{\nu}_{i,t_{i,j-1}} = \frac{\sigma_\epsilon^2}{1-\rho} + o_p(1)$ . Similarly, we can show that  $\frac{1}{\sqrt{m}} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \tilde{\nu}_{i,t_{i,j-1}} \left( \tilde{x}_{i,t_{i,j}} - \rho \tilde{x}_{i,t_{i,j-1}} \right) =$

$O_p(1)$ ,  $\frac{1}{\sqrt{m}} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \tilde{\epsilon}_{i,t_{i,j}} \tilde{x}_{i,t_{i,j-1}} = O_p(1)$ ,  $\frac{1}{m} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} (\tilde{x}_{i,t_{i,j}} - \rho \tilde{x}_{i,t_{i,j-1}}) \tilde{x}_{i,t_{i,j-1}} = O_p(1)$  and  $\sqrt{n} (\hat{\beta}_{FE} - \beta) = O_p(1)$  under the assumptions stated in the Theorem. Hence

$$\frac{1}{m} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} (\hat{\nu}_{i,t_{i,j}} - \rho \hat{\nu}_{i,t_{i,j-1}}) \hat{\nu}_{i,t_{i,j-1}} = O_p\left(\frac{N}{m}\right)$$

Therefore, we have

$$\begin{aligned} \hat{\rho} - \rho &= \frac{\frac{1}{m} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} (\hat{\nu}_{i,t_{i,j}} - \rho \hat{\nu}_{i,t_{i,j-1}}) \hat{\nu}_{i,t_{i,j-1}}}{\frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \hat{\nu}_{i,t_{i,j}}^2} \\ &\quad + \rho \left( \frac{\frac{1}{m} \sum_{i=1}^N \sum_{t_{i,j} \in T(1)} \hat{\nu}_{i,t_{i,j-1}}^2 - \frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \hat{\nu}_{i,t_{i,j}}^2}{\frac{1}{n} \sum_{i=1}^N \sum_{j=1}^{n_i} \hat{\nu}_{i,t_{i,j}}^2} \right) \\ &= O_p\left(\frac{N}{m}\right) + O_p\left(\frac{1}{m}\right) = O_p\left(\frac{N}{m}\right). \end{aligned}$$

■
